Standard Operating Procedure
Bureau of Land and Water Quality
Date: 12/1/2009
Doc. Num.: DEPLW-0970A

1. **Applicability.** The models are applicable to benthic diatom samples collected from rocks or logs in streams and river segments with open to partly open canopy and less than 1.25 meters in depth.
2. **Purpose.** This standard operating procedure describes two multiple regression models, the Diatom Total Phosphorus Index (DTPI) and Diatom Total Nitrogen Index (DTNI), that use benthic diatom community data to estimate concentrations of total phosphorus (TP) and total nitrogen (TN) in Maine streams and rivers. The DTPI and DTNI will be used to help determine attainment of water quality standards. The models will also be used to track water quality over time in response to increased pollution or restoration activities.

3. Definitions

- A. **Benthic Algae.** Algae growing on substrates on the stream bottom.
- B. **Diatom.** Algae in the class Bacillariophyceae.
- C. **Inference Model.** A statistical tool that uses species composition data collected from a waterbody to estimate the value of an environmental variable in the waterbody, such as pH or nutrient concentrations.
- D. **Regression Model.** A statistical model that uses one or more variables as input to predict the likely value for a dependent variable.

4. Responsibilities

- A. **Data Collection and Submission.** Algae must be collected by qualified personnel following Maine Department of Environmental Protection's (DEP) standard operating procedures (Danielson 2006) or comparable method. Algal samples must be processed and diatoms must be identified and enumerated following the protocols set forth the North American Water Quality Assessment (NAWQA) program of the U.S. Geological Survey (Charles et al. 2002) or comparable method. Data must be submitted in Electronic Data Deliverable (EDD) format for uploading into the Environmental Geographic Analysis Database (EGAD).
- B. **Model Calculations.** Data must be checked for quality assurance purposes by qualified DEP staff. Data can then be loaded into EGAD to run the model calculations.

5. Guidelines and Procedures

- A. **Introduction.** Diatoms are commonly used to measure the impacts of nutrient enrichment on water quality. The availability of nutrients is one of the key factors determining which diatoms can survive in a stream. Some diatoms are usually only collected in low-nutrient streams, some are restricted to high-nutrient streams, and others

have broad nutrient preferences. *Tabellaria flocculosa* is an example of a species that is most common in low nutrient streams and decreases in abundance with nutrient enrichment (Figure 1). In contrast, *Navicula trivialis* is an example of a high-nutrient diatom that increases in abundance with nutrient enrichment (Figure 1).

Diatom communities are better indicators of nutrient enrichment than water samples. Water samples can provide incomplete estimates of nutrient enrichment because they represent discrete moments in time. Nutrient concentrations, especially of phosphorus, can fluctuate in developed watersheds because of increased non-point source pollution and stream bank erosion following rain storms. Several water samples may not effectively represent the cumulative supply of nutrients over time because of the variation in concentrations. In contrast, diatom communities develop and are exposed to nutrients over a period of weeks or months. The cumulative supply of nutrients can influence which species can survive and can shape the overall community structure.

Nutrient inference models estimate nutrient concentrations in a stream by using diatom abundances and their nutrient preferences. They are based on overall patterns in species composition. A diatom sample consisting of mostly low-nutrient diatoms will have a low estimated nutrient concentration. In contrast, a diatom sample consisting of mostly high-nutrient diatoms will have a high estimated nutrient concentration.

Figure 1. *Tabellaria flocculosa* (left) and *Navicula trivialis* (right).

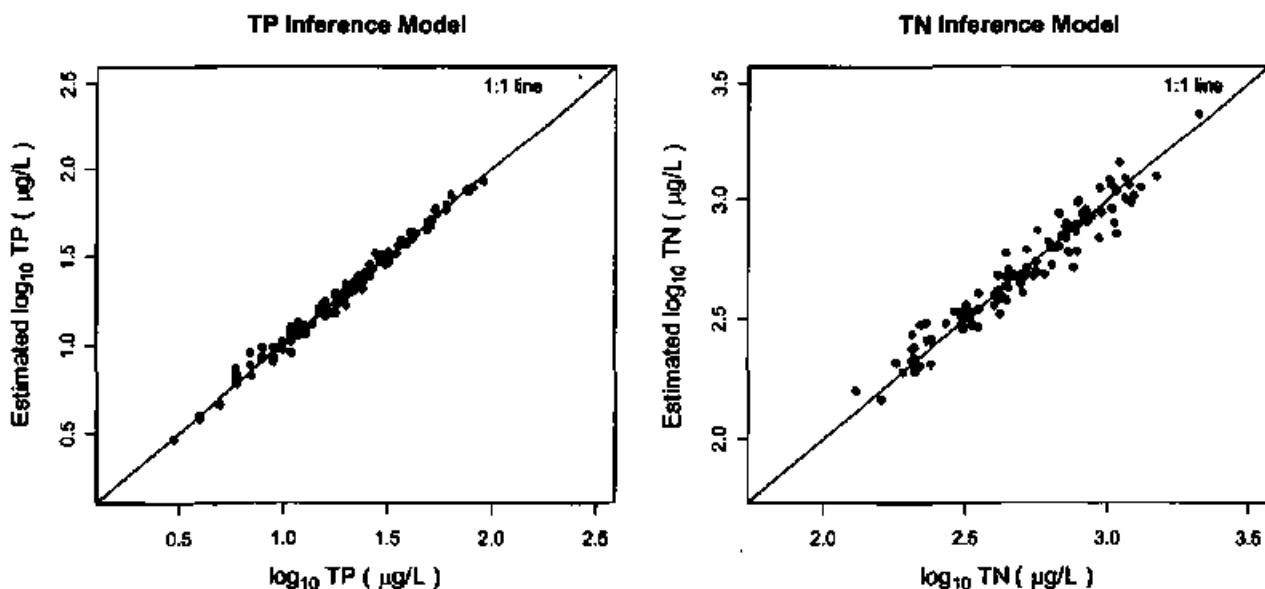

- B. Model Development.** The models were developed by assembling 123 samples from streams across the state. The streams ranged from low-nutrient streams to high-nutrient streams. Data included TN and TP concentrations from stream water and diatoms collected by scraping rocks in the streams. A variety of statistical models were tested and a multiple linear regression approach was ultimately selected because of its performance and ease of calculation. Linear regression uses a simple formula to describe a straight-line relationship between two variables: $Y = \beta_1 x + \beta_0$. Y is the dependent or response variable that is predicted, x is the independent or explanatory variable, β is the coefficient

for the explanatory variable, and β_0 is the constant. Multiple regression follows the same approach but uses more than one explanatory variable.

The DTPI and DTNI are regression models that use many species as independent variables in the calculations. A statistical technique called forward stepwise selection was used to identify the combination of species that provide the best estimate of the observed TP and TN concentrations. The statistical application took the diatom and nutrient data and iteratively added species and assigned the species coefficients (i.e., β). It selected the combination of species and their coefficients that best predicted the nutrient concentrations in a straight line with the least amount of scatter around the line.

Two measurements were used to measure how well the models fit a straight line. The r^2 value measures the strength of the association and the root mean square error (RMSE) measures the amount of scatter around the line. A perfect relationship would have an r^2 approaching 1 and a RMSE approaching 0. The worst relationship would have a r^2 approaching 0 and a very high RMSE. The adjusted r^2 and RMSE of the TP model were 0.90 and 0.10 respectively (Figure 2). The adjusted r^2 and RMSE of the TN model were 0.91 and 0.07 respectively. DTPI and DTNI models were tested with another set of 75 samples with r^2 values of 0.50 and 0.31 respectively. Overall, the performance of the Maine models is comparable to nutrient inference models developed for New Jersey (Ponader et al. 2007, Ponader et al. 2008), the Northern Piedmont Region of the U.S. (Potapova et al. 2004), and western U.S. (Stevenson et al. 2008).

Figure 2: TP and TN inference models for Maine streams and rivers.

C. Data Preparation

- 1) **Exclude Rare Species.** Rare species can reduce the predictive quality of inference models because calculating their nutrient preferences is difficult. The models were built using a subset of 209 of the most common diatom species (Table 1). New calculations need to be based on the same subset of 209 diatoms to be consistent with the way the models were developed. Including rare species would change the percent abundances of the common taxa. Therefore, any taxa that are present in a sample but are not included in Table 1 are excluded.
- 2) **Calculate Square Root of Percent Abundances.** Once species not included in Table 1 are removed, the next step is to convert the species counts to percent abundances as shown in Table 2. Diatom abundances are based on the density of cells per square centimeter of substrate sampled.
 - i. Divide the abundance of each species in a sample by the total abundance of all species in the sample that are listed in Table 1.
 - ii. The next step is to calculate the square root of the abundances. The models use the square roots of percent abundances to reduce the influence of a few ubiquitous and abundant diatoms such as *Achnanthidium minutissimum*.

D. Diatom Total Phosphorus Index (DTPI)

- 1) **Exclude Taxa without TP Coefficients.** Only include those species with TP coefficients in Table 1 when calculating the DTPI as shown in Table 2.
- 2) **Model Formula.** $TP^* = 1.322585 + \sum_i x_i \beta_i^{TP}$
 - i. TP^* is the \log_{10} TP ($\mu\text{g/L}$)
 - ii. Σ is the symbol for summation.
 - iii. x_i is the square root percent abundance of species i
 - iv. β_i^{TP} is the TP coefficient of species i in Table 1
- 3) **Applicable Range.** Index values outside of the ranges specified below must be treated with caution since they are beyond the scope of the original models. In

In addition, extreme values can be caused by atypical diatom communities. The applicable range for TP^* is between 0.4 and 2.1.

- 4) **Convert Results.** The final step is to convert TP^* from \log_{10} units to normal units as shown in Table 2. This is accomplished by using the following formula:

$$DTPI = \text{Estimated TP } (\mu\text{g/L}) = 10^{TP^*}$$

E. Diatom Total Nitrogen Index (DTNI)

- 1) **Exclude Taxa Without TN Coefficients.** Only include those species with TN coefficients when calculating the DTNI (Table 1).
- 2) **Model Formula.** $TN^* = 2.245248 + \sum_i x_i \beta_i^{TN}$
 - i. TN^* is the \log_{10} TN ($\mu\text{g/L}$)
 - ii. Σ is the symbol for summation.
 - iii. x_i is the square root percent abundance of species i
 - iv. β_i^{TN} is the TN coefficient of species i in Table 1
- 3) **Applicable Range.** Index values outside of the ranges specified below must be treated with caution since they are beyond the scope of the original models. In addition, extreme values can be caused by atypical diatom communities. The applicable range of TN^* is between 2.1 and 3.4.
- 4) **Convert Results.** The final step is to convert TN^* from \log_{10} units to normal units. This is accomplished by using the following formula:

$$DTNI = \text{Estimated TN } (\mu\text{g/L}) = 10^{TN^*}$$

<i>Fragilaria vaucheriae</i> var. <i>capitellata</i>	0.2	0.404		
<i>Gomphonema acuminatum</i>	0.3	0.572		
<i>Gomphonema parvulum</i>	2.6	1.617		
<i>Gomphonema truncatum</i>	0.3	0.572		
<i>Navicula notha</i>	0.5	0.700	-0.063641	-0.044558
<i>Nitzschia fonticola</i>	not in Table 1			
<i>Nitzschia inconspicua</i>	0.2	0.404	0.161569	0.065310
<i>Synedra ulna</i>	5.1	2.251		
<i>Tabellaria flocculosa</i>	0.3	0.572		

$TN^* = \text{constant} + \text{sum of products} = 2.391341$

$DTNI = 10^{TN^*} = 10^{2.391341} = 246.2 \mu\text{g/L}$
